Today's Agenda

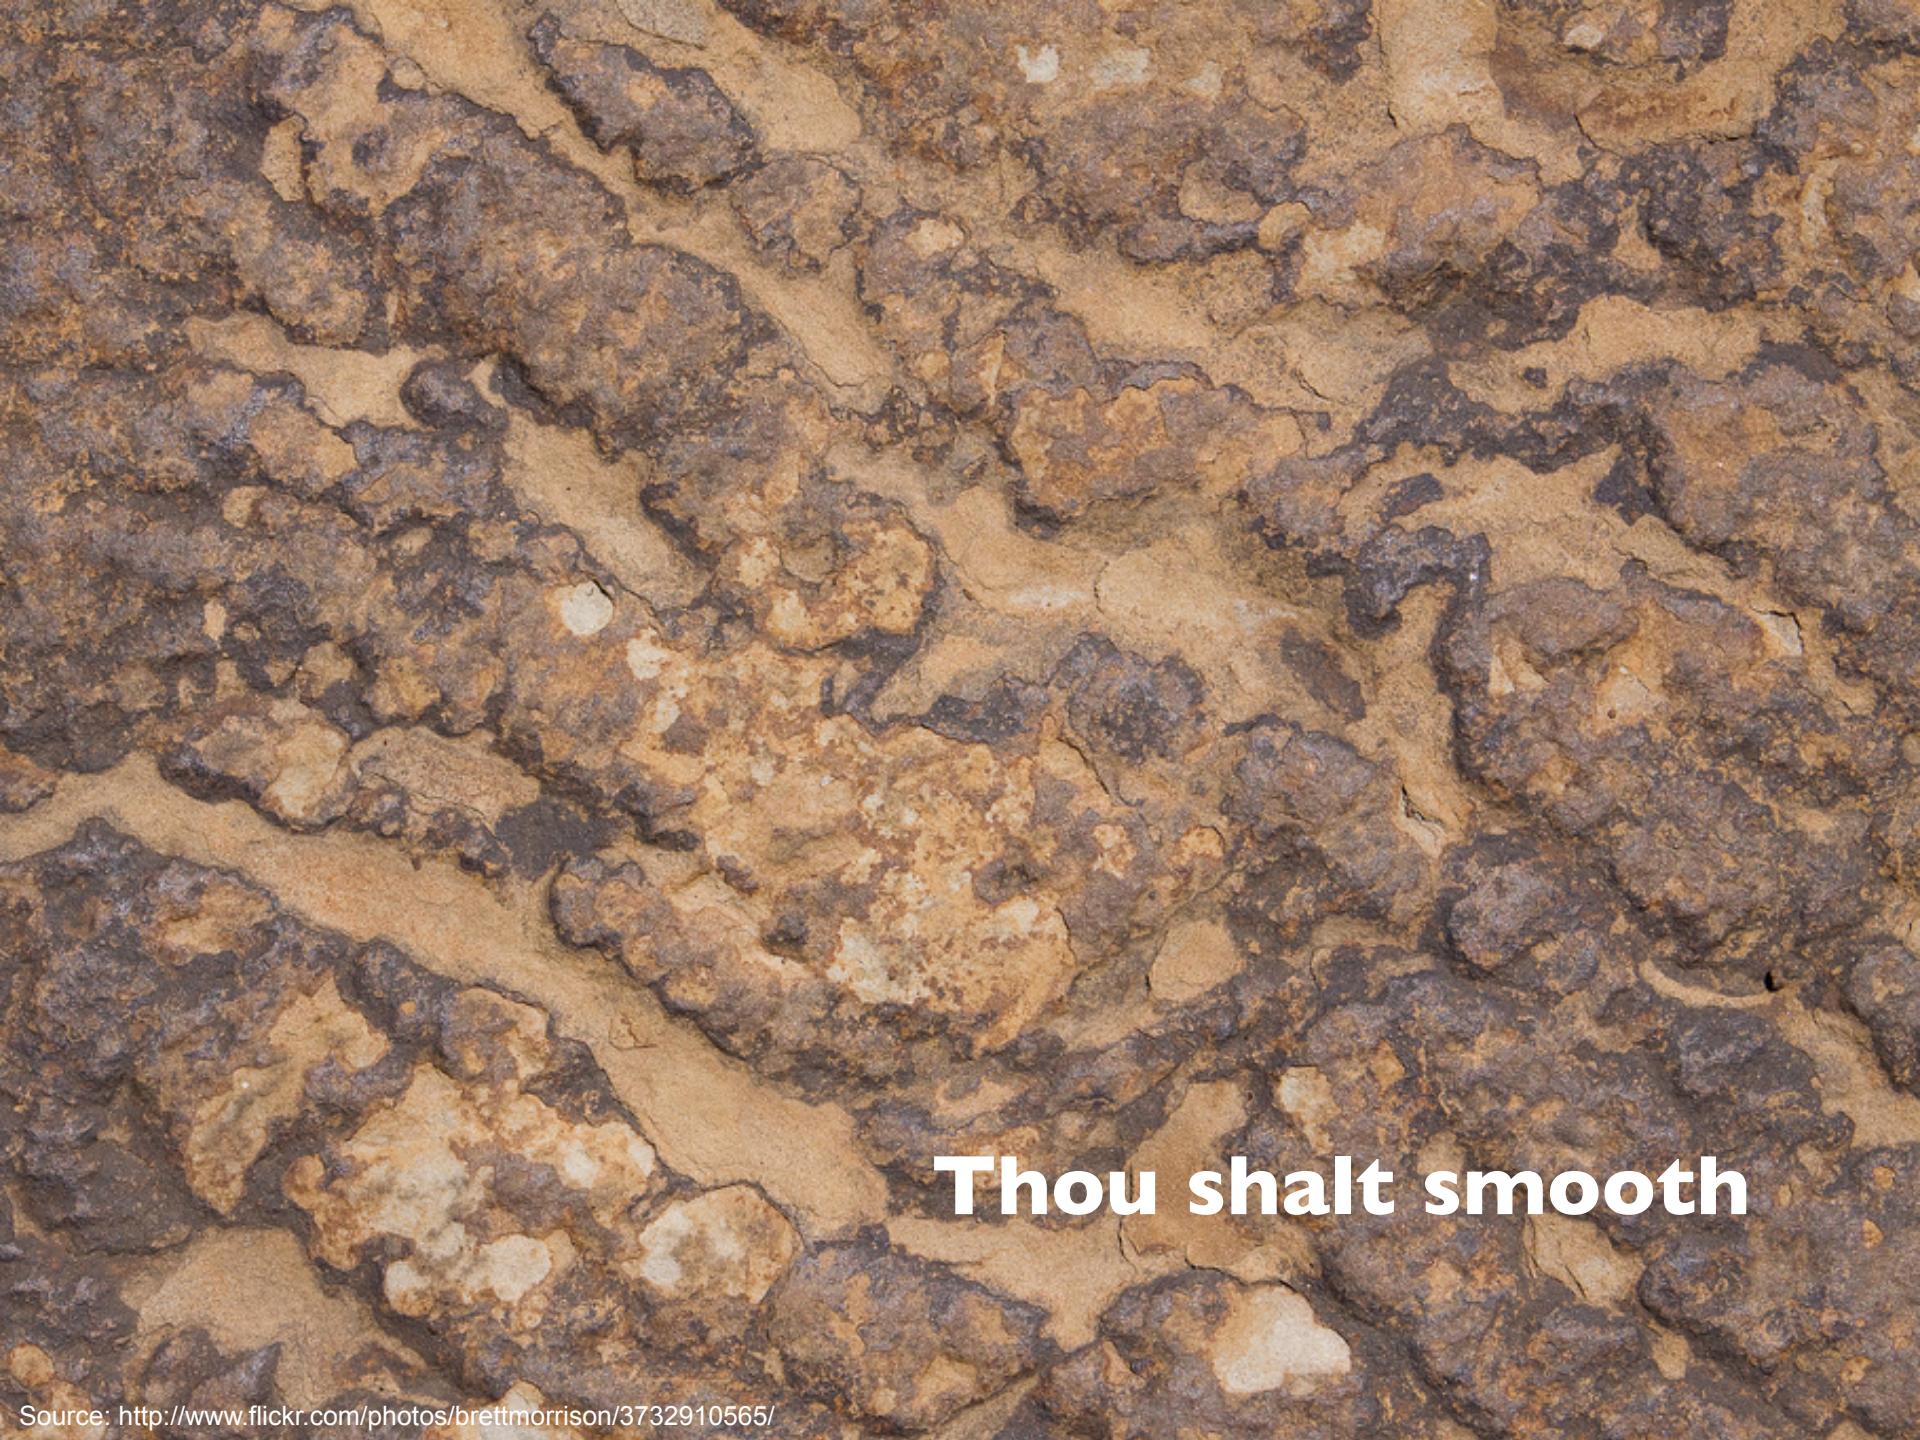

- Real-world word counting: language models
 - How to break all the rules and get away with it
- Crash course on information retrieval
 - Basics of indexing and retrieval
 - Inverted indexing in MapReduce

The two commandments of estimating probability distributions...

Probabilities must sum up to one

Thou shalt smooth

MapReduce

A wide-angle photograph of a massive server room, likely a Google data center. The room is filled with floor-to-ceiling server racks, their front panels glowing with various colors (blue, yellow, green) from integrated LED lights. A complex network of grey metal walkways and support structures spans the entire space, with stairs leading up to different levels. The ceiling is a dark, multi-layered steel truss structure with recessed lighting. The overall atmosphere is cool and industrial, with a strong blue tint from the artificial lighting.

Count. Normalize.

Count.

```
1: class MAPPER
2:     method MAP(docid a, doc d)
3:         for all term t ∈ doc d do
4:             EMIT(term t, count 1)

1: class REDUCER
2:     method REDUCE(term t, counts [c1, c2, ...])
3:         sum ← 0
4:         for all count c ∈ counts [c1, c2, ...] do
5:             sum ← sum + c
6:         EMIT(term t, count s)
```

What's the non-toy application of word count?

Language Models

$$P(w_1, w_2, \dots, w_T)$$

$$= P(w_1)P(w_2|w_1)P(w_3|w_1, w_2)\dots P(w_T|w_1, \dots, w_{T-1})$$

[chain rule]

Is this tractable?

Approximating Probabilities

Basic idea: limit history to fixed number of words N
(Markov Assumption)

$$P(w_k | w_1, \dots, w_{k-1}) \approx P(w_k | w_{k-N+1}, \dots, w_{k-1})$$

N=1: Unigram Language Model

$$P(w_k | w_1, \dots, w_{k-1}) \approx P(w_k)$$

$$\Rightarrow P(w_1, w_2, \dots, w_T) \approx P(w_1)P(w_2) \dots P(w_T)$$

Approximating Probabilities

Basic idea: limit history to fixed number of words N
(Markov Assumption)

$$P(w_k | w_1, \dots, w_{k-1}) \approx P(w_k | w_{k-N+1}, \dots, w_{k-1})$$

N=2: Bigram Language Model

$$P(w_k | w_1, \dots, w_{k-1}) \approx P(w_k | w_{k-1})$$

$$\Rightarrow P(w_1, w_2, \dots, w_T) \approx P(w_1 | \text{S}) P(w_2 | w_1) \dots P(w_T | w_{T-1})$$

Approximating Probabilities

Basic idea: limit history to fixed number of words N
(Markov Assumption)

$$P(w_k | w_1, \dots, w_{k-1}) \approx P(w_k | w_{k-N+1}, \dots, w_{k-1})$$

N=3: Trigram Language Model

$$P(w_k | w_1, \dots, w_{k-1}) \approx P(w_k | w_{k-2}, w_{k-1})$$

$$\Rightarrow P(w_1, w_2, \dots, w_T) \approx P(w_1 | \text{S} > < \text{S} >) \dots P(w_T | w_{T-2} w_{T-1})$$

Building N -Gram Language Models

- Compute maximum likelihood estimates (MLE) for individual n -gram probabilities

- Unigram: $P(w_i) = \frac{C(w_i)}{N}$

- Bigram: $P(w_i, w_j) = \frac{C(w_i, w_j)}{N}$

$$P(w_j|w_i) = \frac{P(w_i, w_j)}{P(w_i)} = \frac{C(w_i, w_j)}{\sum_w C(w_i, w)} = \frac{C(w_i, w_j)}{C(w_i)}$$

- Generalizes to higher-order n -grams
- We already know how to do this in MapReduce!

Thou shalt smooth!

- Zeros are bad for any statistical estimator
 - Need better estimators because MLEs give us a lot of zeros
 - A distribution without zeros is “smoother”
- The Robin Hood Philosophy: Take from the rich (seen n -grams) and give to the poor (unseen n -grams)
 - And thus also called discounting
 - Make sure you still have a valid probability distribution!
- Lots of techniques:
 - Laplace, Good-Turing, Katz backoff, Jelinek-Mercer
 - Kneser-Ney represents best practice

Stupid Backoff

- Let's break all the rules:

$$S(w_i | w_{i-k+1}^{i-1}) = \begin{cases} \frac{f(w_{i-k+1}^i)}{f(w_{i-k+1}^{i-1})} & \text{if } f(w_{i-k+1}^i) > 0 \\ \alpha S(w_i | w_{i-k+2}^{i-1}) & \text{otherwise} \end{cases}$$

$$S(w_i) = \frac{f(w_i)}{N}$$

- But throw *lots* of data at the problem!

Stupid Backoff Implementation

- Same basic idea as “pairs” approach discussed previously
- A few optimizations:
 - Convert words to integers, ordered by frequency
(take advantage of VByte compression)
 - Replicate unigram counts to all shards

Stupid Backoff Implementation

- Straightforward approach: count each order separately

A B ← remember this value

A B C

A B D

A B E

...

- More clever approach: count *all* orders together

A B ← remember this value

A B C ← remember this value

A B C P

A B C Q

A B D ← remember this value

A B D X

A B D Y

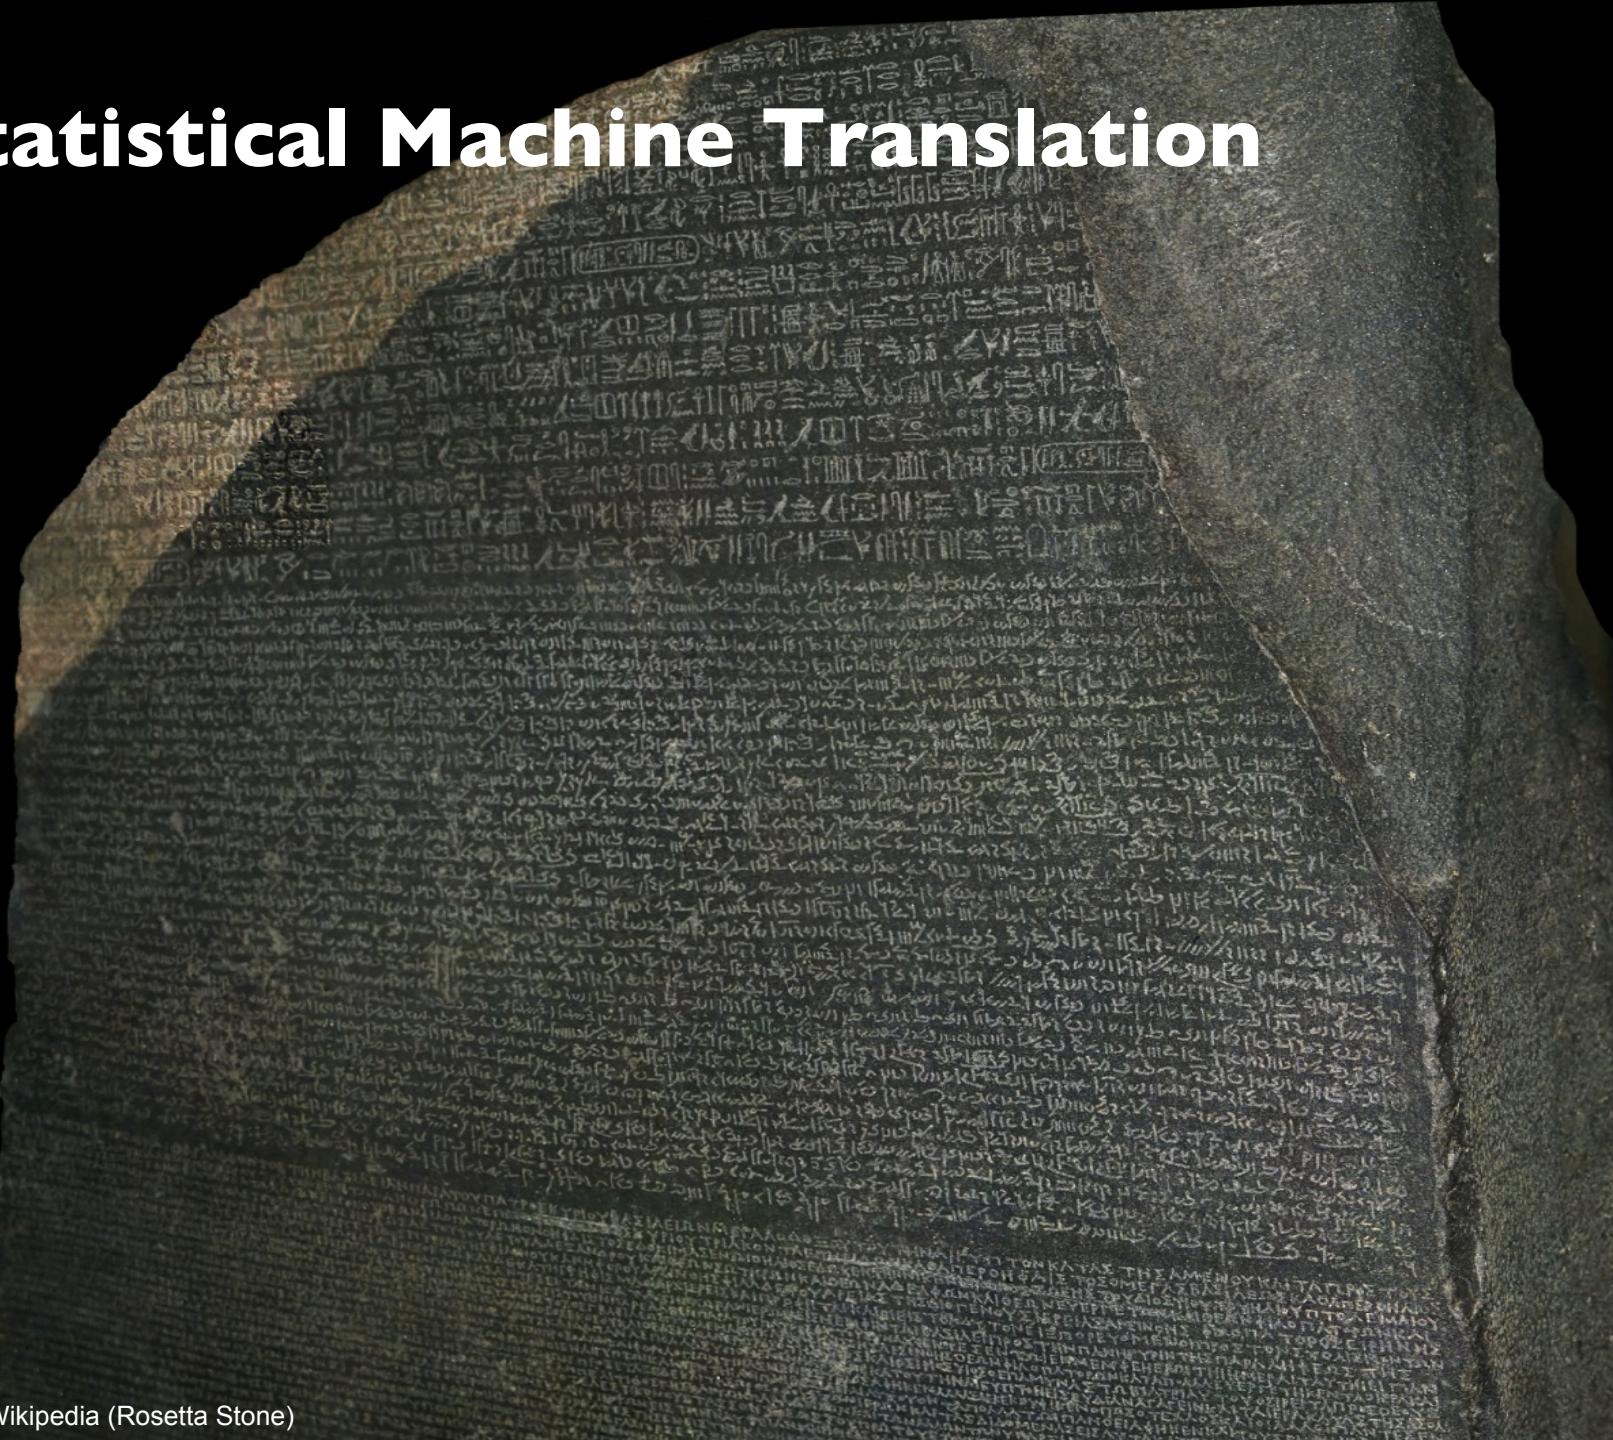

...

State of the art smoothing (less data)

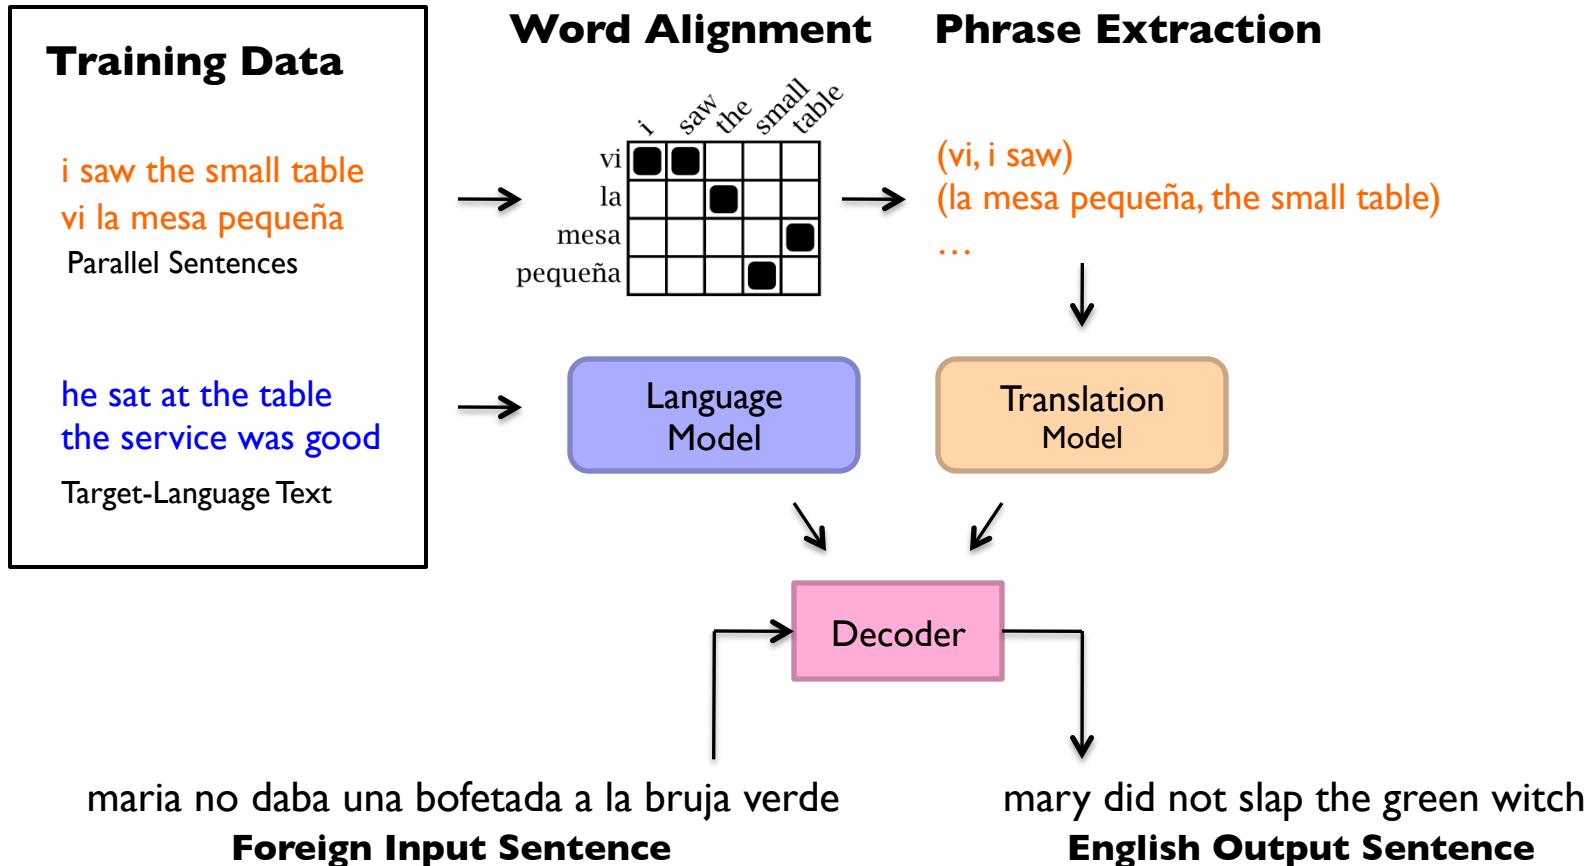

vs. Count and normalize (more data)

Statistical Machine Translation

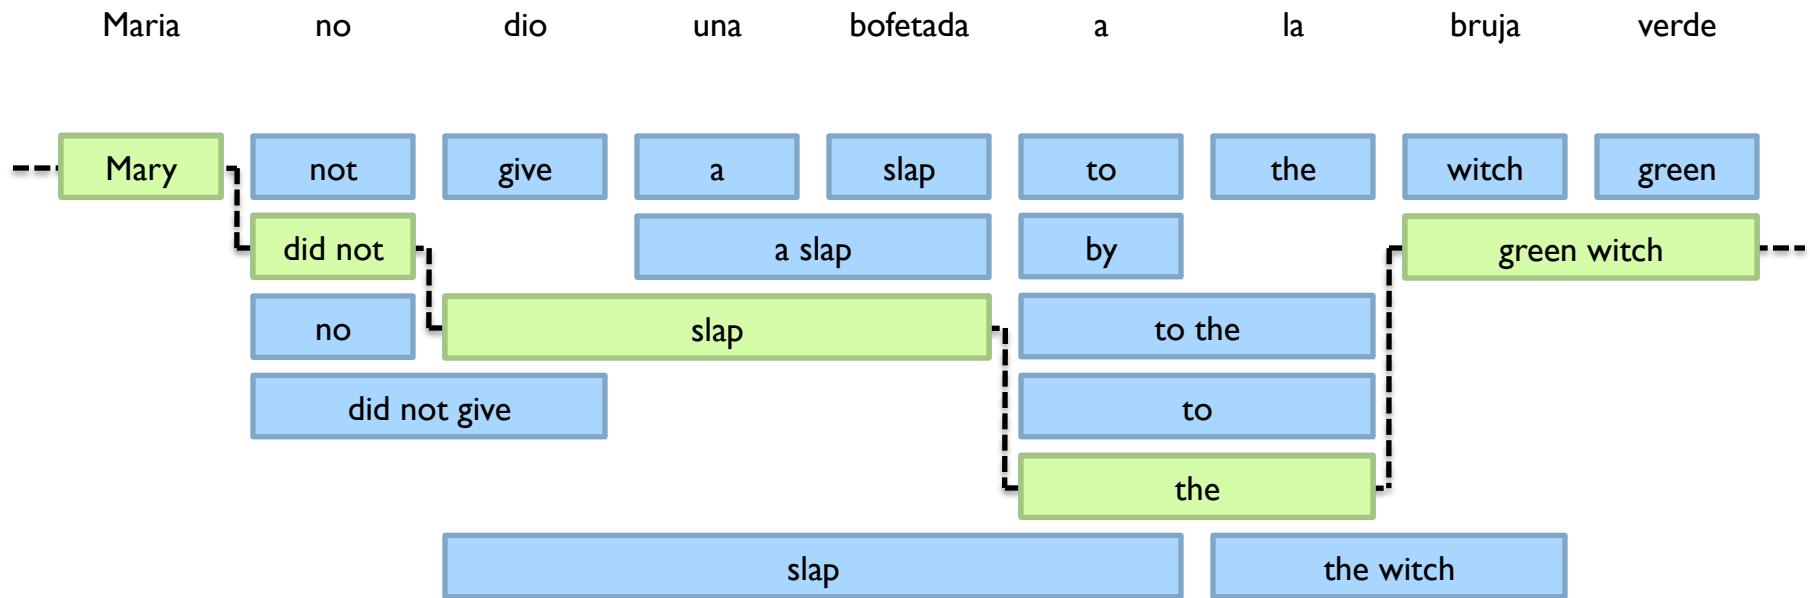

Statistical Machine Translation

$$\hat{e}_1^I = \arg \max_{e_1^I} [P(e_1^I | f_1^J)] = \arg \max_{e_1^I} [P(e_1^I) P(f_1^J | e_1^I)]$$

Translation as a Tiling Problem

$$\hat{e}_1^I = \arg \max_{e_1^I} [P(e_1^I | f_1^J)] = \arg \max_{e_1^I} [P(e_1^I) P(f_1^J | e_1^I)]$$

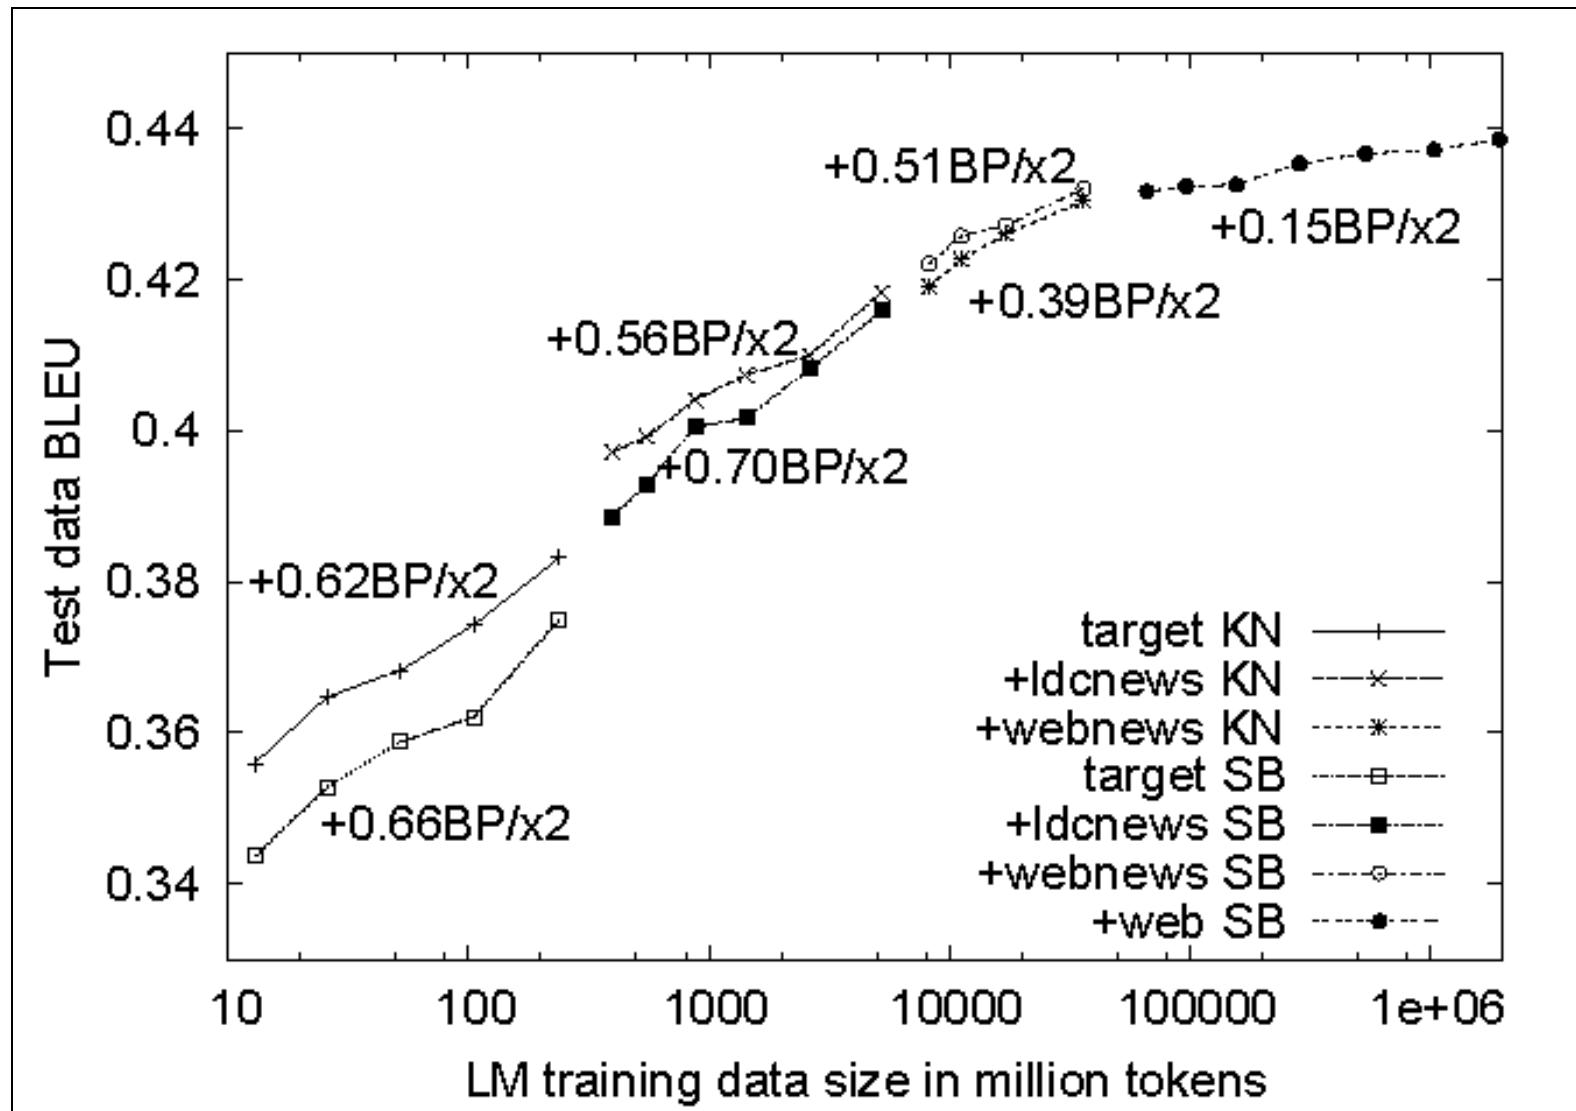

$$P(e|f) = \frac{P(e) \cdot P(f|e)}{P(f)}$$

$$\hat{e} = \arg \max_e P(e)P(f|e)$$

Results: Running Time

	<i>target</i>	<i>webnews</i>	<i>web</i>
# tokens	237M	31G	1.8T
vocab size	200k	5M	16M
# <i>n</i> -grams	257M	21G	300G
LM size (SB)	2G	89G	1.8T
time (SB)	20 min	8 hours	1 day
time (KN)	2.5 hours	2 days	–
# machines	100	400	1500

Results: Translation Quality

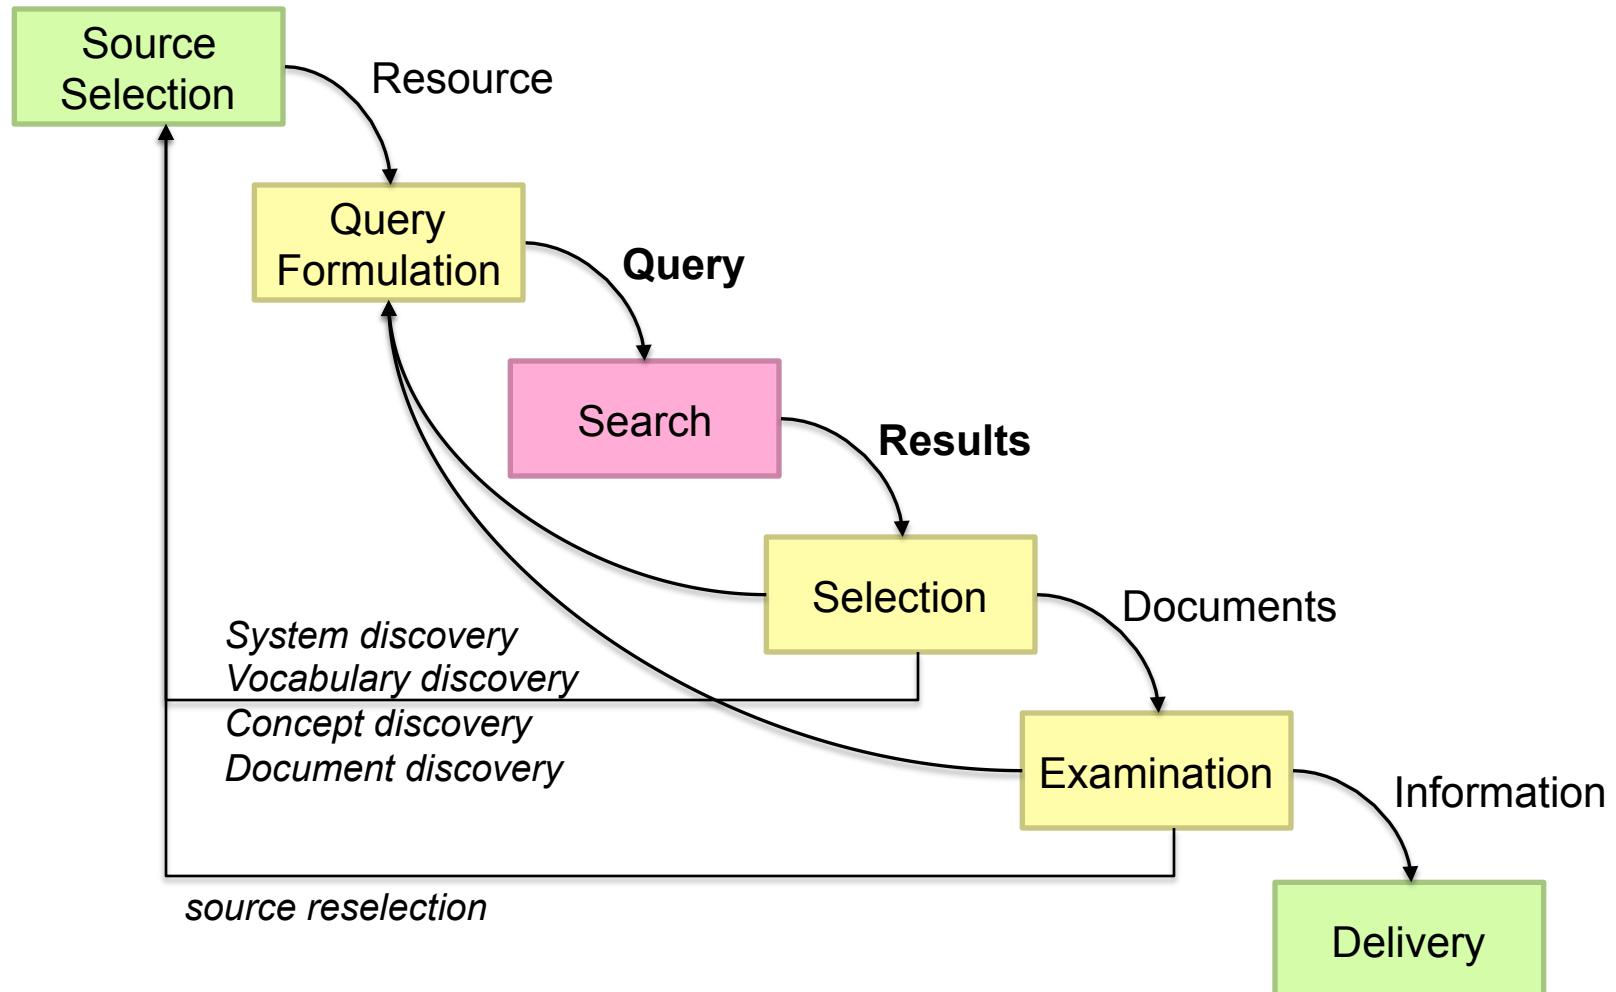

Today's Agenda

- Real-world word counting: language models
 - How to break all the rules and get away with it
- Crash course on information retrieval
 - Basics of indexing and retrieval
 - Inverted indexing in MapReduce

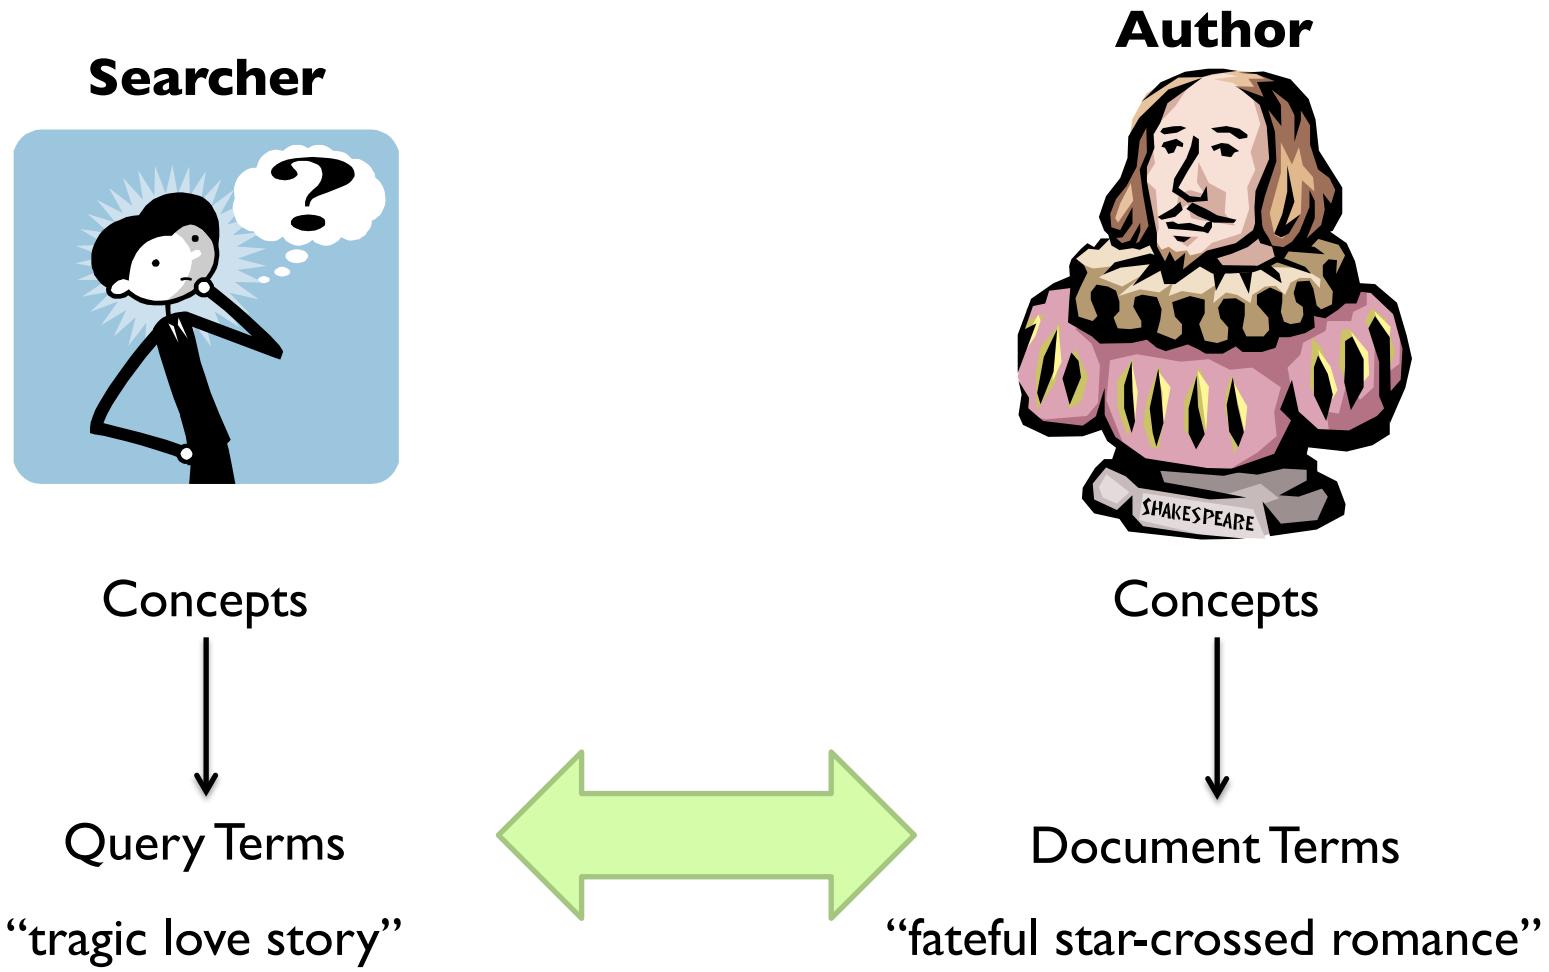

First, nomenclature...

- Information retrieval (IR)
 - Focus on textual information (= text/document retrieval)
 - Other possibilities include image, video, music, ...
- What do we search?
 - Generically, “collections”
 - Less-frequently used, “corpora”
- What do we find?
 - Generically, “documents”
 - Even though we may be referring to web pages, PDFs, PowerPoint slides, paragraphs, etc.

Information Retrieval Cycle

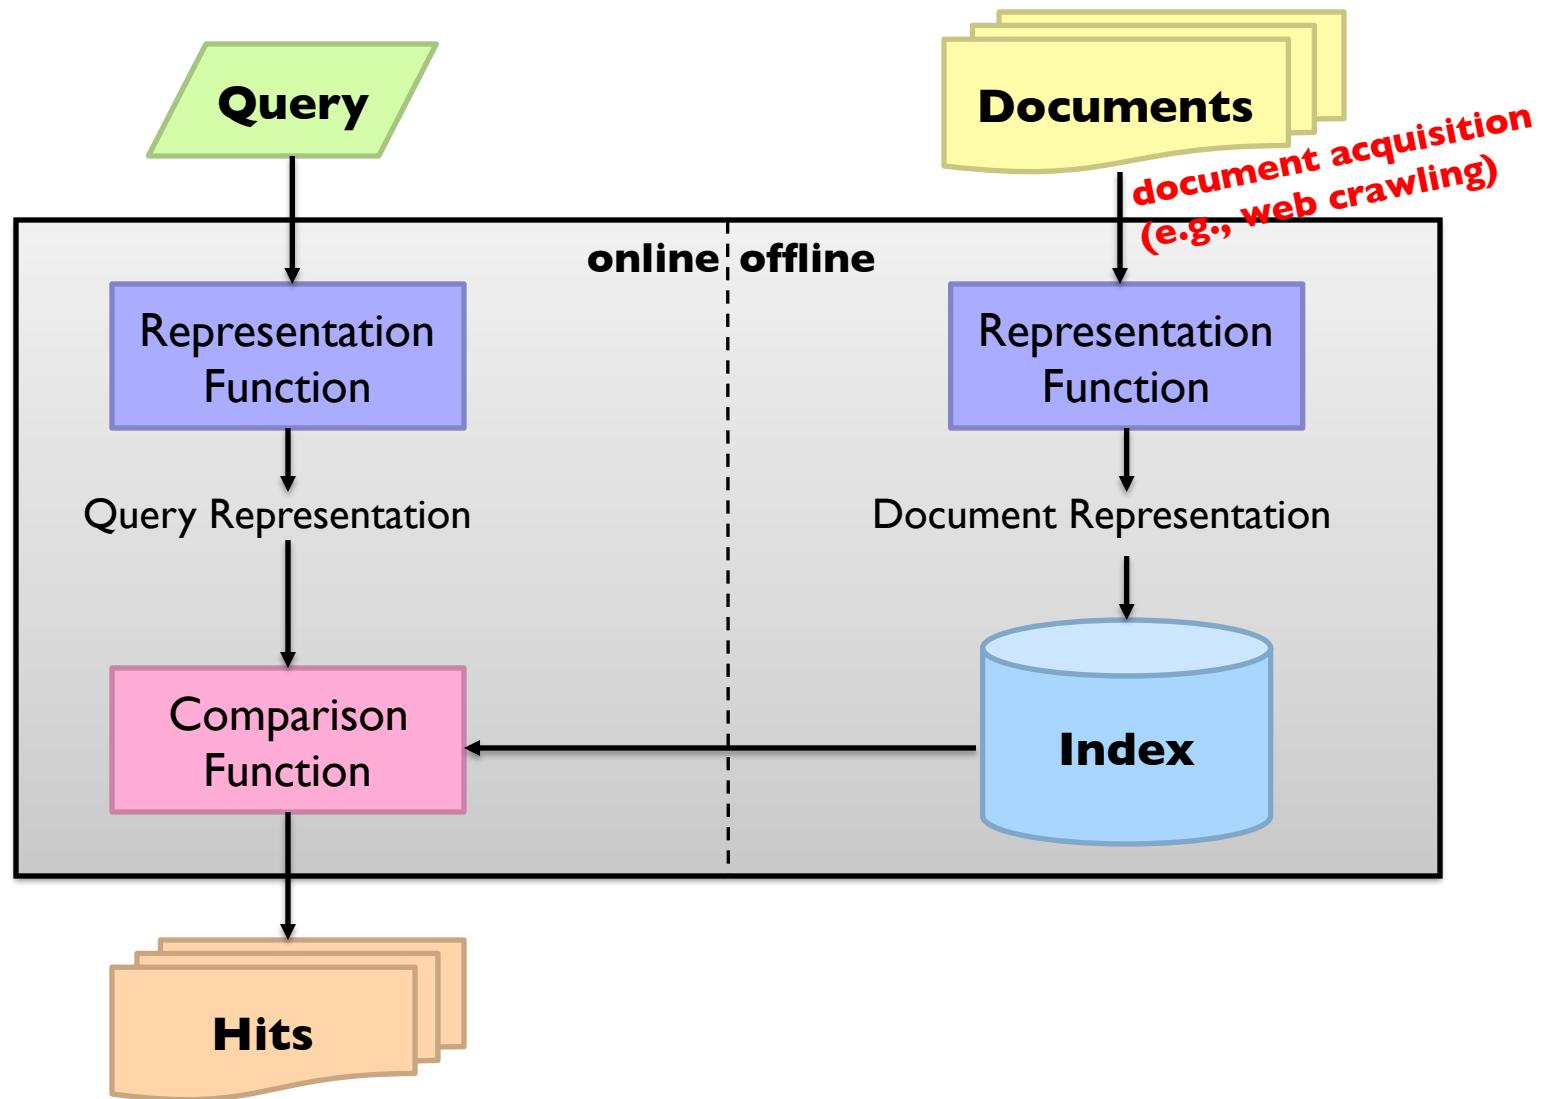

The Central Problem in Search

Do these represent the same concepts?

Abstract IR Architecture

How do we represent text?

- Remember: computers don't "understand" anything!
- "Bag of words"
 - Treat all the words in a document as index terms
 - Assign a "weight" to each term based on "importance" (or, in simplest case, presence/absence of word)
 - Disregard order, structure, meaning, etc. of the words
 - Simple, yet effective!
- Assumptions
 - Term occurrence is independent
 - Document relevance is independent
 - "Words" are well-defined

What's a word?

天主教教宗若望保祿二世因感冒再度住進醫院。
這是他今年第二度因同樣的病因住院。

وقال مارك ريجيف - الناطق باسم

군대라도 동원해 막고싶은 심정"이라고 말했다는 일부 언론의 보도를 부인했다.

Sample Document

McDonald's slims down spuds

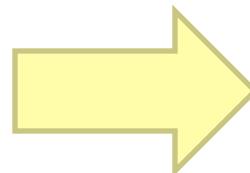

Fast-food chain to reduce certain types of fat in its french fries with new cooking oil.

NEW YORK (CNN/Money) - McDonald's Corp. is cutting the amount of "bad" fat in its french fries nearly in half, the fast-food chain said Tuesday as it moves to make all its fried menu items healthier.

But does that mean the popular shoestring fries won't taste the same? The company says no. "It's a win-win for our customers because they are getting the same great french-fry taste along with an even healthier nutrition profile," said Mike Roberts, president of McDonald's USA.

But others are not so sure. McDonald's will not specifically discuss the kind of oil it plans to use, but at least one nutrition expert says playing with the formula could mean a different taste.

Shares of Oak Brook, Ill.-based McDonald's (MCD: down \$0.54 to \$23.22, Research, Estimates) were lower Tuesday afternoon. It was unclear Tuesday whether competitors Burger King and Wendy's International (WEN: down \$0.80 to \$34.91, Research, Estimates) would follow suit. Neither company could immediately be reached for comment.

"Bag of Words"

14 × McDonalds

12 × fat

11 × fries

8 × new

7 × french

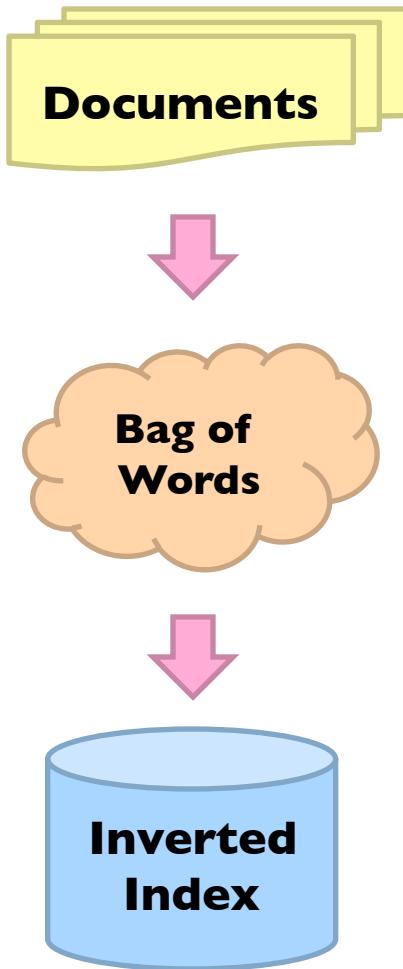

6 × company, said, nutrition

5 × food, oil, percent, reduce, taste, Tuesday

...

...

Counting Words...

case folding, tokenization, stopword removal, stemming

✗ syntax, semantics, word knowledge, etc.

Boolean Retrieval

- Users express queries as a Boolean expression
 - AND, OR, NOT
 - Can be arbitrarily nested
- Retrieval is based on the notion of sets
 - Any given query divides the collection into two sets: retrieved, not-retrieved
 - Pure Boolean systems do not define an ordering of the results

Inverted Index: Boolean Retrieval

egg				1
fish	1	1		
green				1
ham				1
hat		1		
one	1			
red		1		
two	1			

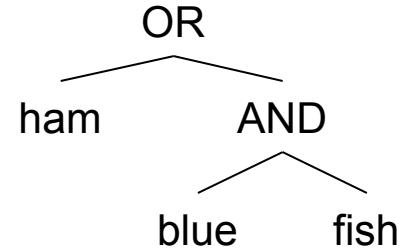

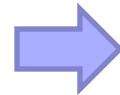

Boolean Retrieval

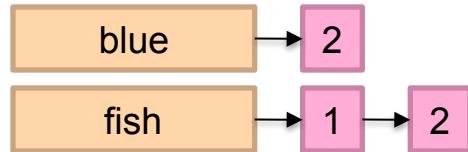

- To execute a Boolean query:

- Build query syntax tree

(blue AND fish) OR ham

- For each clause, look up postings

- Traverse postings and apply Boolean operator

- Efficiency analysis

- Postings traversal is linear (assuming sorted postings)
 - Start with shortest posting first

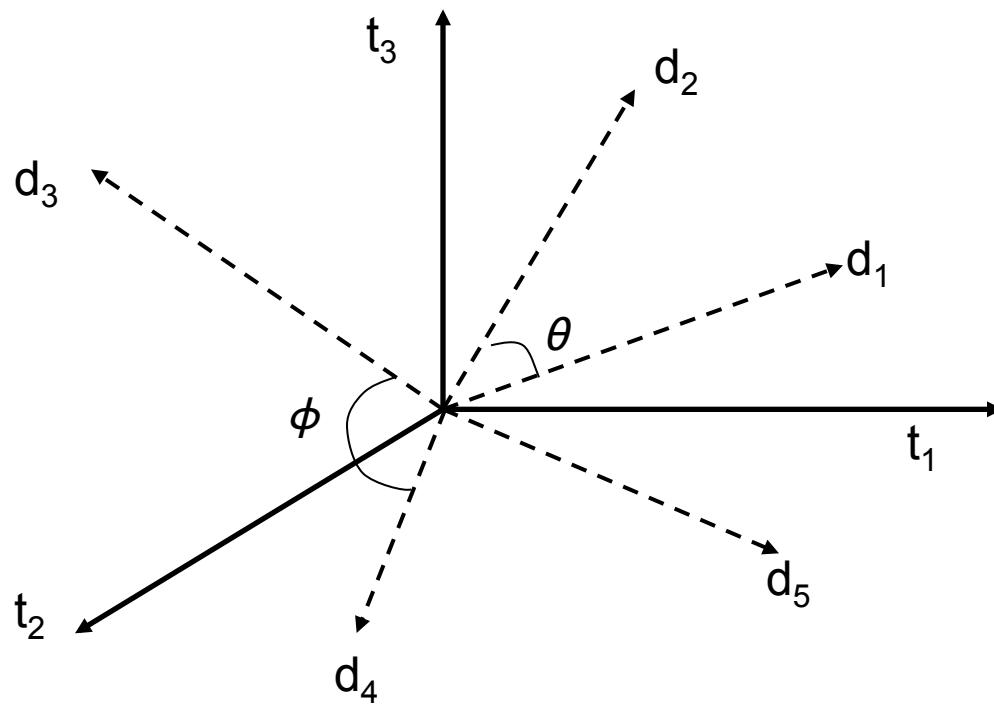

Strengths and Weaknesses

- Strengths
 - Precise, if you know the right strategies
 - Precise, if you have an idea of what you're looking for
 - Implementations are fast and efficient
- Weaknesses
 - Users must learn Boolean logic
 - Boolean logic insufficient to capture the richness of language
 - No control over size of result set: either too many hits or none
 - **When do you stop reading?** All documents in the result set are considered “equally good”
 - **What about partial matches?** Documents that “don’t quite match” the query may be useful also

Ranked Retrieval

- Order documents by how likely they are to be relevant
 - Estimate relevance(q, d_i)
 - Sort documents by relevance
 - Display sorted results
- User model
 - Present hits one screen at a time, best results first
 - At any point, users can decide to stop looking
- How do we estimate relevance?
 - Assume document is relevant if it has a lot of query terms
 - Replace relevance(q, d_i) with sim(q, d_i)
 - Compute similarity of vector representations

Vector Space Model

Assumption: Documents that are “close together” in vector space “talk about” the same things

Therefore, retrieve documents based on how close the document is to the query (i.e., similarity \sim “closeness”)

Similarity Metric

- Use “angle” between the vectors:

$$\cos(\theta) = \frac{\vec{d}_j \cdot \vec{d}_k}{\|\vec{d}_j\| \|\vec{d}_k\|}$$

$$sim(d_j, d_k) = \frac{\vec{d}_j \cdot \vec{d}_k}{\|\vec{d}_j\| \|\vec{d}_k\|} = \frac{\sum_{i=1}^n w_{i,j} w_{i,k}}{\sqrt{\sum_{i=1}^n w_{i,j}^2} \sqrt{\sum_{i=1}^n w_{i,k}^2}}$$

- Or, more generally, inner products:

$$sim(d_j, d_k) = \vec{d}_j \cdot \vec{d}_k = \sum_{i=1}^n w_{i,j} w_{i,k}$$

Term Weighting

- Term weights consist of two components
 - Local: how important is the term in this document?
 - Global: how important is the term in the collection?
- Here's the intuition:
 - Terms that appear often in a document should get high weights
 - Terms that appear in many documents should get low weights
- How do we capture this mathematically?
 - Term frequency (local)
 - Inverse document frequency (global)

TF.IDF Term Weighting

$$w_{i,j} = \text{tf}_{i,j} \cdot \log \frac{N}{n_i}$$

$w_{i,j}$ weight assigned to term i in document j

$\text{tf}_{i,j}$ number of occurrence of term i in document j

N number of documents in entire collection

n_i number of documents with term i

Inverted Index: TF.IDF

Positional Indexes

- Store term position in postings
- Supports richer queries (e.g., proximity)
- Naturally, leads to larger indexes...

two	→ 1 → 1 1 [3]

Retrieval in a Nutshell

- Look up postings lists corresponding to query terms
- Traverse postings for each query term
- Store partial query-document scores in accumulators
- Select top k results to return

Retrieval: Document-at-a-Time

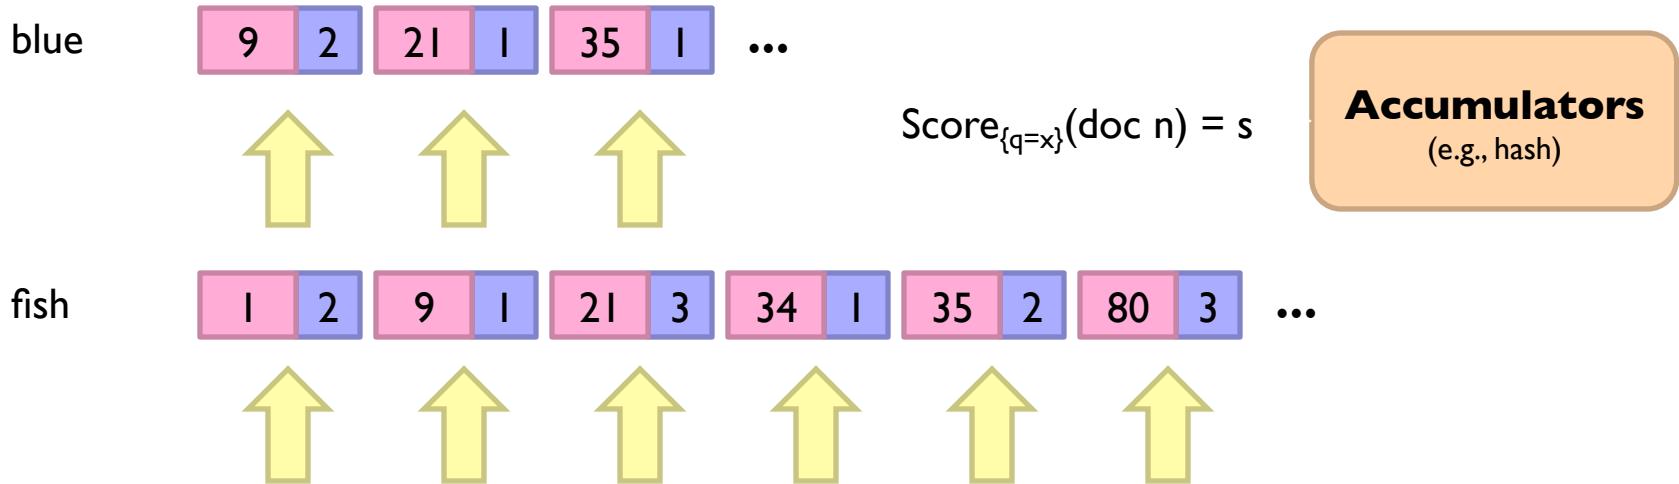

- Evaluate documents one at a time (score all query terms)

- Tradeoffs
 - Small memory footprint (good)
 - Must read through all postings (bad), but skipping possible
 - More disk seeks (bad), but blocking possible

Retrieval: Query-At-A-Time

- Evaluate documents one query term at a time
 - Usually, starting from most rare term (often with tf-sorted postings)

- Tradeoffs
 - Early termination heuristics (good)
 - Large memory footprint (bad), but filtering heuristics possible

MapReduce it?

- The indexing problem
 - Scalability is critical
 - Must be relatively fast, but need not be real time
 - Fundamentally a batch operation
 - Incremental updates may or may not be important
 - For the web, crawling is a challenge in itself
- The retrieval problem
 - Must have sub-second response time
 - For the web, only need relatively few results

Perfect for MapReduce!

Uh... not so good...

Indexing: Performance Analysis

- Fundamentally, a large sorting problem
 - Terms usually fit in memory
 - Postings usually don't
- How is it done on a single machine?
- How can it be done with MapReduce?
- First, let's characterize the problem size:
 - Size of vocabulary
 - Size of postings

Vocabulary Size: Heaps' Law

$$M = kT^b$$

M is vocabulary size

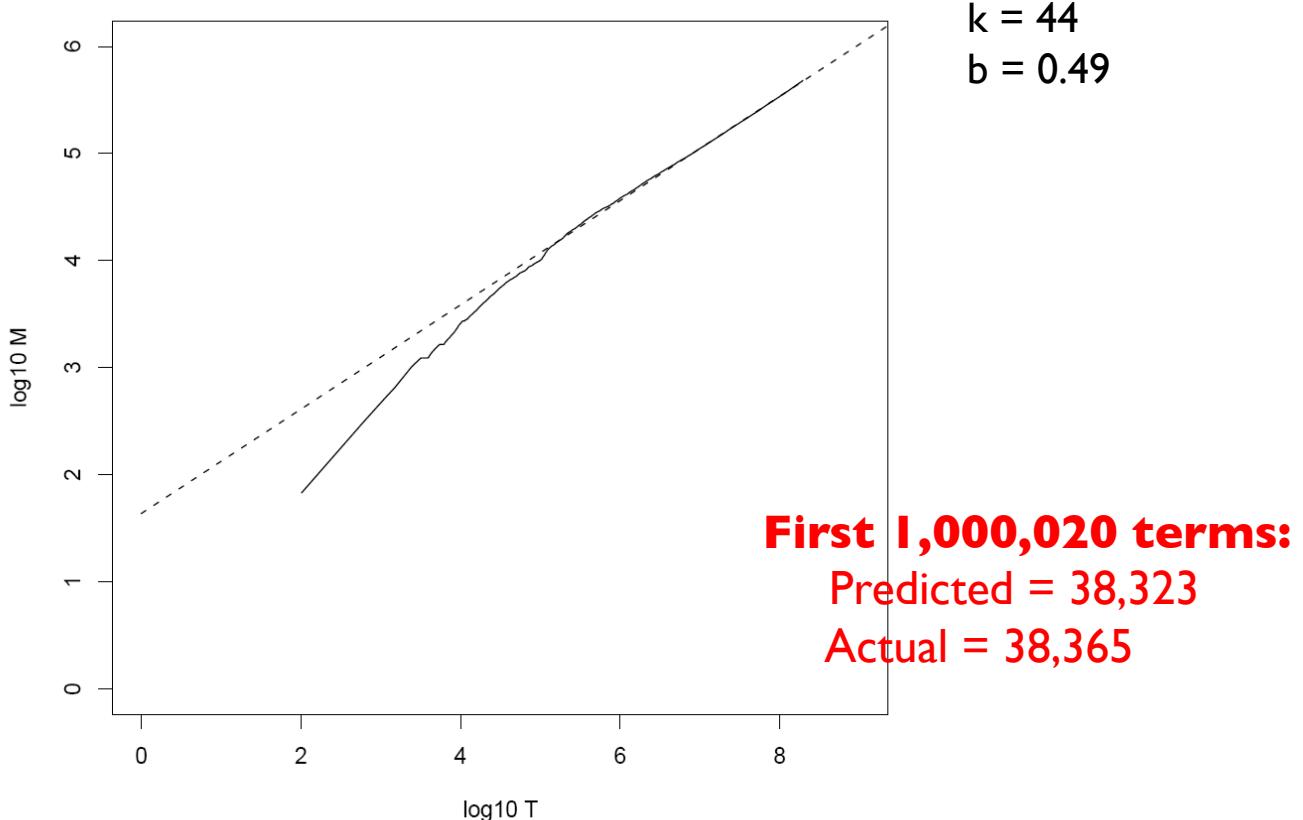

T is collection size (number of documents)

k and b are constants

Typically, k is between 30 and 100, b is between 0.4 and 0.6

- Heaps' Law: linear in log-log space
- Vocabulary size grows unbounded!

Heaps' Law for RCVI

Reuters-RCVI collection: 806,791 newswire documents (Aug 20, 1996-August 19, 1997)

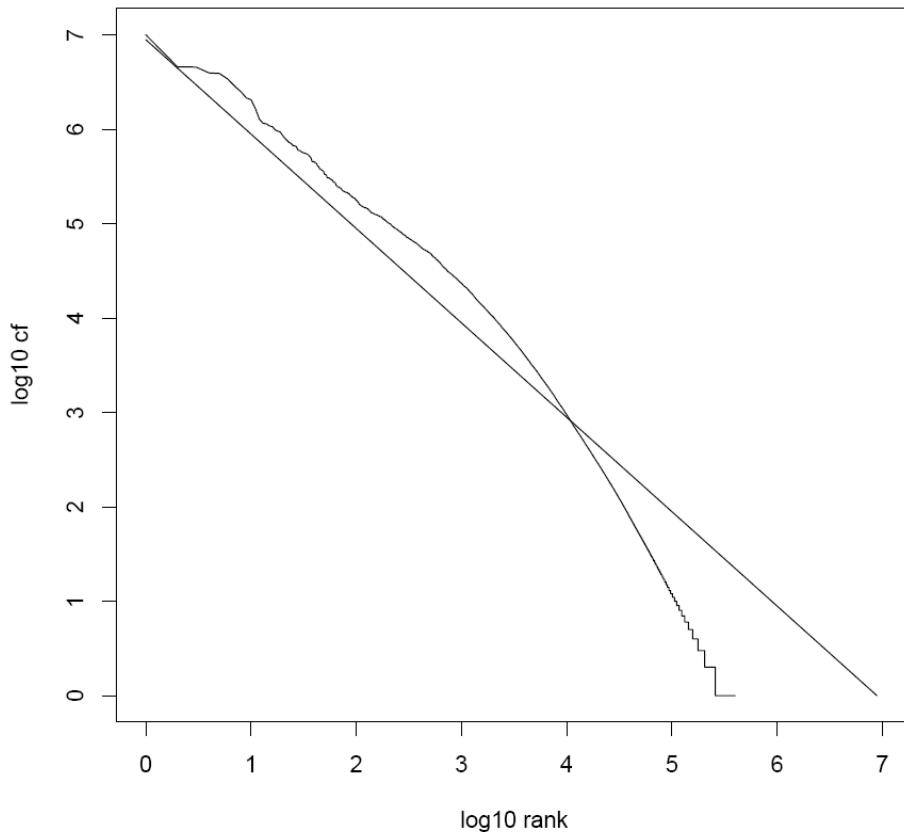

Postings Size: Zipf's Law

$$cf_i = \frac{c}{i}$$

cf is the collection frequency of i -th common term
c is a constant

- Zipf's Law: (also) linear in log-log space
 - Specific case of Power Law distributions
- In other words:
 - A few elements occur very frequently
 - Many elements occur very infrequently

Zipf's Law for RCVI

Fit isn't that good...
but good enough!

Reuters-RCVI collection: 806,791 newswire documents (Aug 20, 1996-August 19, 1997)

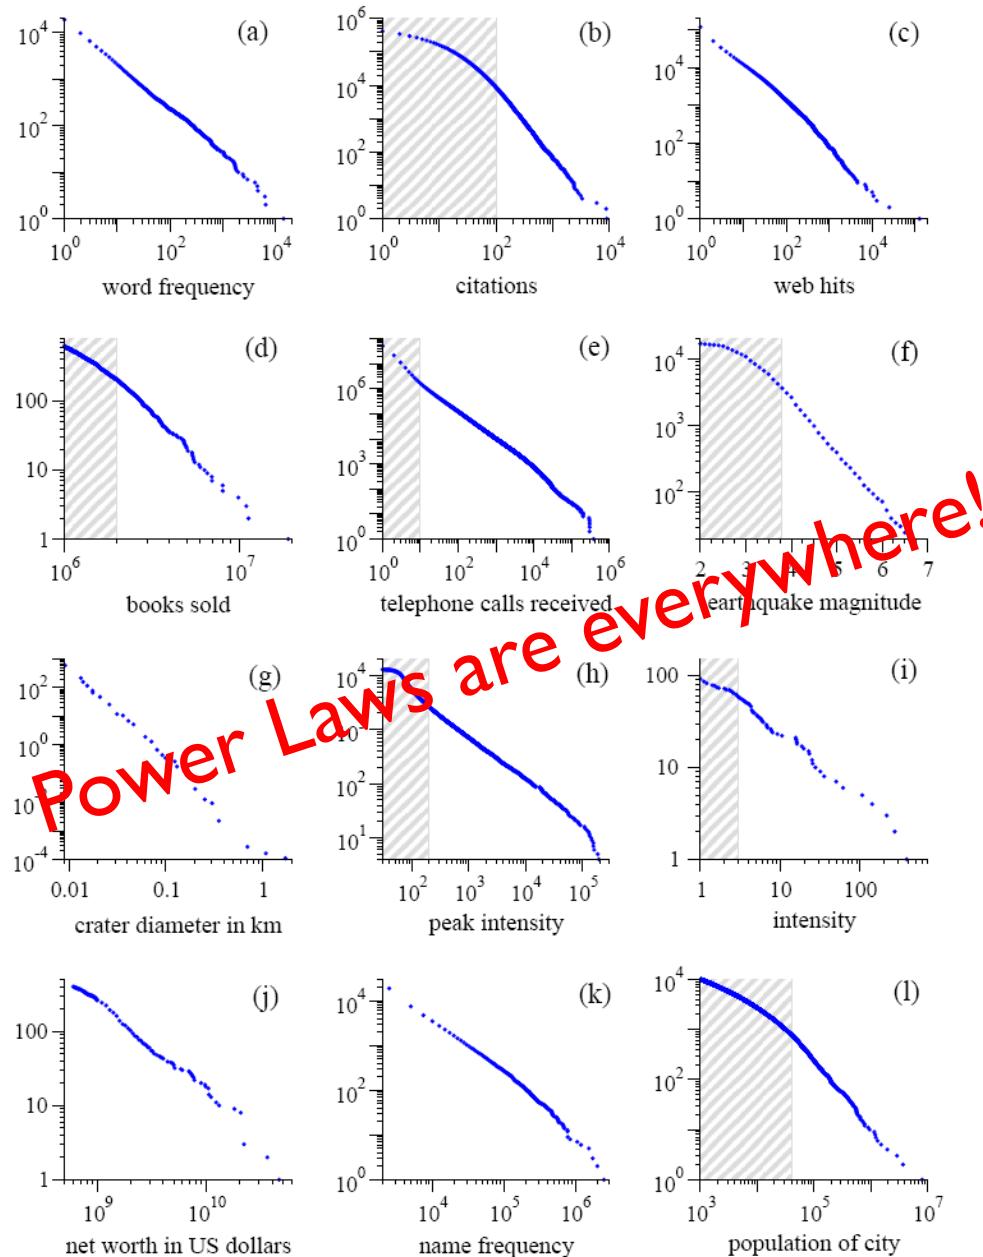

Figure from: Newman, M. E. J. (2005) "Power laws, Pareto distributions and Zipf's law." *Contemporary Physics* 46:323–351.

MapReduce: Index Construction

- Map over all documents
 - Emit *term* as key, $(docno, tf)$ as value
 - Emit other information as necessary (e.g., term position)
- Sort/shuffle: group postings by term
- Reduce
 - Gather and sort the postings (e.g., by *docno* or *tf*)
 - Write postings to disk
- MapReduce does all the heavy lifting!

Inverted Indexing with MapReduce

3:     P  $\leftarrow$  new LIST
4:     for all posting  $\langle a, f \rangle \in$  postings [ $\langle a_1, f_1 \rangle, \langle a_2, f_2 \rangle \dots$ ] do
5:       APPEND(P,  $\langle a, f \rangle$ )
6:     SORT(P)
7:     EMIT(term t, postings P)
```

What's the problem?

Scalability Bottleneck

- Initial implementation: terms as keys, postings as values
 - Reducers must buffer all postings associated with key (to sort)
 - What if we run out of memory to buffer postings?
- Uh oh!

Another Try...

(key)	(values)
fish	1 2 [2,4]
	34 1 [23]
	21 3 [1,8,22]
	35 2 [8,41]
	80 3 [2,9,76]
	9 1 [9]

(keys)	(values)
fish	1 [2,4]
fish	9 [9]
fish	21 [1,8,22]
fish	34 [23]
fish	35 [8,41]
fish	80 [2,9,76]

How is this different?

- Let the framework do the sorting
- Term frequency implicitly stored
- Directly write postings to disk!

Where have we seen this before?

Postings Encoding

Conceptually:

fish 

In Practice:

- Don't encode docnos, encode gaps (or d -gaps)
- But it's not obvious that this save space...

fish 

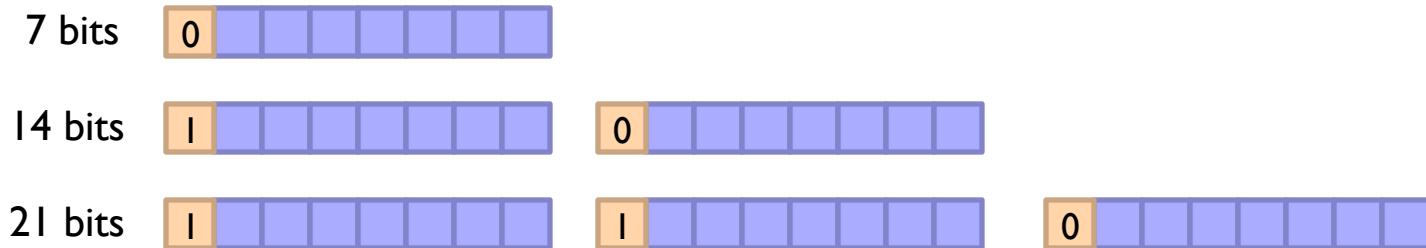

Overview of Index Compression

- Byte-aligned vs. bit-aligned
- Byte-aligned technique
 - VByte
 - Simple9 and variants
 - PForDelta
- Non-parameterized bit-aligned
 - Unary codes
 - γ codes
 - δ codes
- Parameterized bit-aligned
 - Golomb codes (local Bernoulli model)

Want more detail? Read *Managing Gigabytes* by Witten, Moffat, and Bell!

VByte

- Simple idea: use only as many bytes as needed
 - Need to reserve one bit per byte as the “continuation bit”
 - Use remaining bits for encoding value

- Works okay, easy to implement...

Unary Codes

- $x \geq 1$ is coded as $x-1$ one bits, followed by 1 zero bit
 - $3 = 110$
 - $4 = 1110$
- Great for small numbers... horrible for large numbers
 - Overly-biased for very small gaps

Watch out! Slightly different definitions in different textbooks

γ codes

- $x \geq 1$ is coded in two parts: length and offset
 - Start with binary encoded, remove highest-order bit = offset
 - Length is number of binary digits, encoded in unary code
 - Concatenate length + offset codes
- Example: 9 in binary is 1001
 - Offset = 001
 - Length = 4, in unary code = 1110
 - γ code = 1110:001
- Analysis
 - Offset = $\lfloor \log x \rfloor$
 - Length = $\lfloor \log x \rfloor + 1$
 - Total = $2 \lfloor \log x \rfloor + 1$

δ codes

- Similar to γ codes, except that length is encoded in γ code
- Example: 9 in binary is 1001
 - Offset = 001
 - Length = 4, in γ code = 11000
 - δ code = 11000:001
- γ codes = more compact for smaller numbers
 δ codes = more compact for larger numbers

Golomb Codes

- $x \geq 1$, parameter b :
 - $q + 1$ in unary, where $q = \lfloor (x - 1) / b \rfloor$
 - r in binary, where $r = x - qb - 1$, in $\lceil \log b \rceil$ or $\lceil \log b \rceil$ bits
- Example:
 - $b = 3, r = 0, 1, 2$ (0, 10, 11)
 - $b = 6, r = 0, 1, 2, 3, 4, 5$ (00, 01, 100, 101, 110, 111)
 - $x = 9, b = 3: q = 2, r = 2$, code = 110:11
 - $x = 9, b = 6: q = 1, r = 2$, code = 10:100
- Optimal $b \approx 0.69$ (N/df)
 - Different b for every term!

Comparison of Coding Schemes

	Unary	γ	δ	Golomb	
				b=3	b=6
1	0	0	0	0:0	0:00
2	10	10:0	100:0	0:10	0:01
3	110	10:1	100:1	0:11	0:100
4	1110	110:00	101:00	10:0	0:101
5	11110	110:01	101:01	10:10	0:110
6	111110	110:10	101:10	10:11	0:111
7	1111110	110:11	101:11	110:0	10:00
8	11111110	1110:000	11000:000	110:10	10:01
9	111111110	1110:001	11000:001	110:11	10:100
10	1111111110	1110:010	11000:010	1110:0	10:101

Index Compression: Performance

Comparison of Index Size (bits per pointer)

	Bible	TREC
Unary	262	1918
Binary	15	20
γ	6.51	6.63
δ	6.23	6.38
Golomb	6.09	5.84

←One of the best techniques

Bible: King James version of the Bible; 31,101 verses (4.3 MB)

TREC: TREC disks 1+2; 741,856 docs (2070 MB)

Chicken and Egg?

	(key)	(value)
fish	1	[2,4]
fish	9	[9]
fish	21	[1,8,22]
fish	34	[23]
fish	35	[8,41]
fish	80	[2,9,76]
	...	

But wait! How do we set the Golomb parameter b ?

Recall: optimal $b \approx 0.69$ (N/df)

We need the df to set b ...

But we don't know the df until we've seen all postings!

Write directly to disk

Sound familiar?

Getting the df

- In the mapper:
 - Emit “special” key-value pairs to keep track of df
- In the reducer:
 - Make sure “special” key-value pairs come first: process them to determine df
- Remember: proper partitioning!

Getting the df: Modified Mapper

Doc 1

one fish, two fish

Input document...

(key) (value)

fish	I	[2,4]	Emit normal key-value pairs...
------	---	-------	--------------------------------

one	I	[!]	
-----	---	-----	--

two	I	[3]	
-----	---	-----	--

fish	★	[!]	Emit “special” key-value pairs to keep track of df...
------	---	-----	---

one	★	[!]	
-----	---	-----	--

two	★	[!]	
-----	---	-----	--

Getting the df: Modified Reducer

(key)	(value)	
fish	★	[63] [82] [27] ...
fish	I	[2,4]
fish	9	[9]
fish	21	[1,8,22]
fish	34	[23]
fish	35	[8,41]
fish	80	[2,9,76]
	...	

First, compute the *df* by summing contributions from all “special” key-value pair...

Compute Golomb parameter *b*...

Important: properly define sort order to make sure “special” key-value pairs come first!

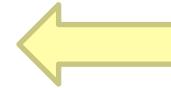

Write postings directly to disk

Where have we seen this before?

MapReduce it?

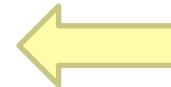

- The indexing problem

Just covered

- Scalability is paramount
- Must be relatively fast, but need not be real time
- Fundamentally a batch operation
- Incremental updates may or may not be important
- For the web, crawling is a challenge in itself

- The retrieval problem

Now

- Must have sub-second response time
- For the web, only need relatively few results

Retrieval with MapReduce?

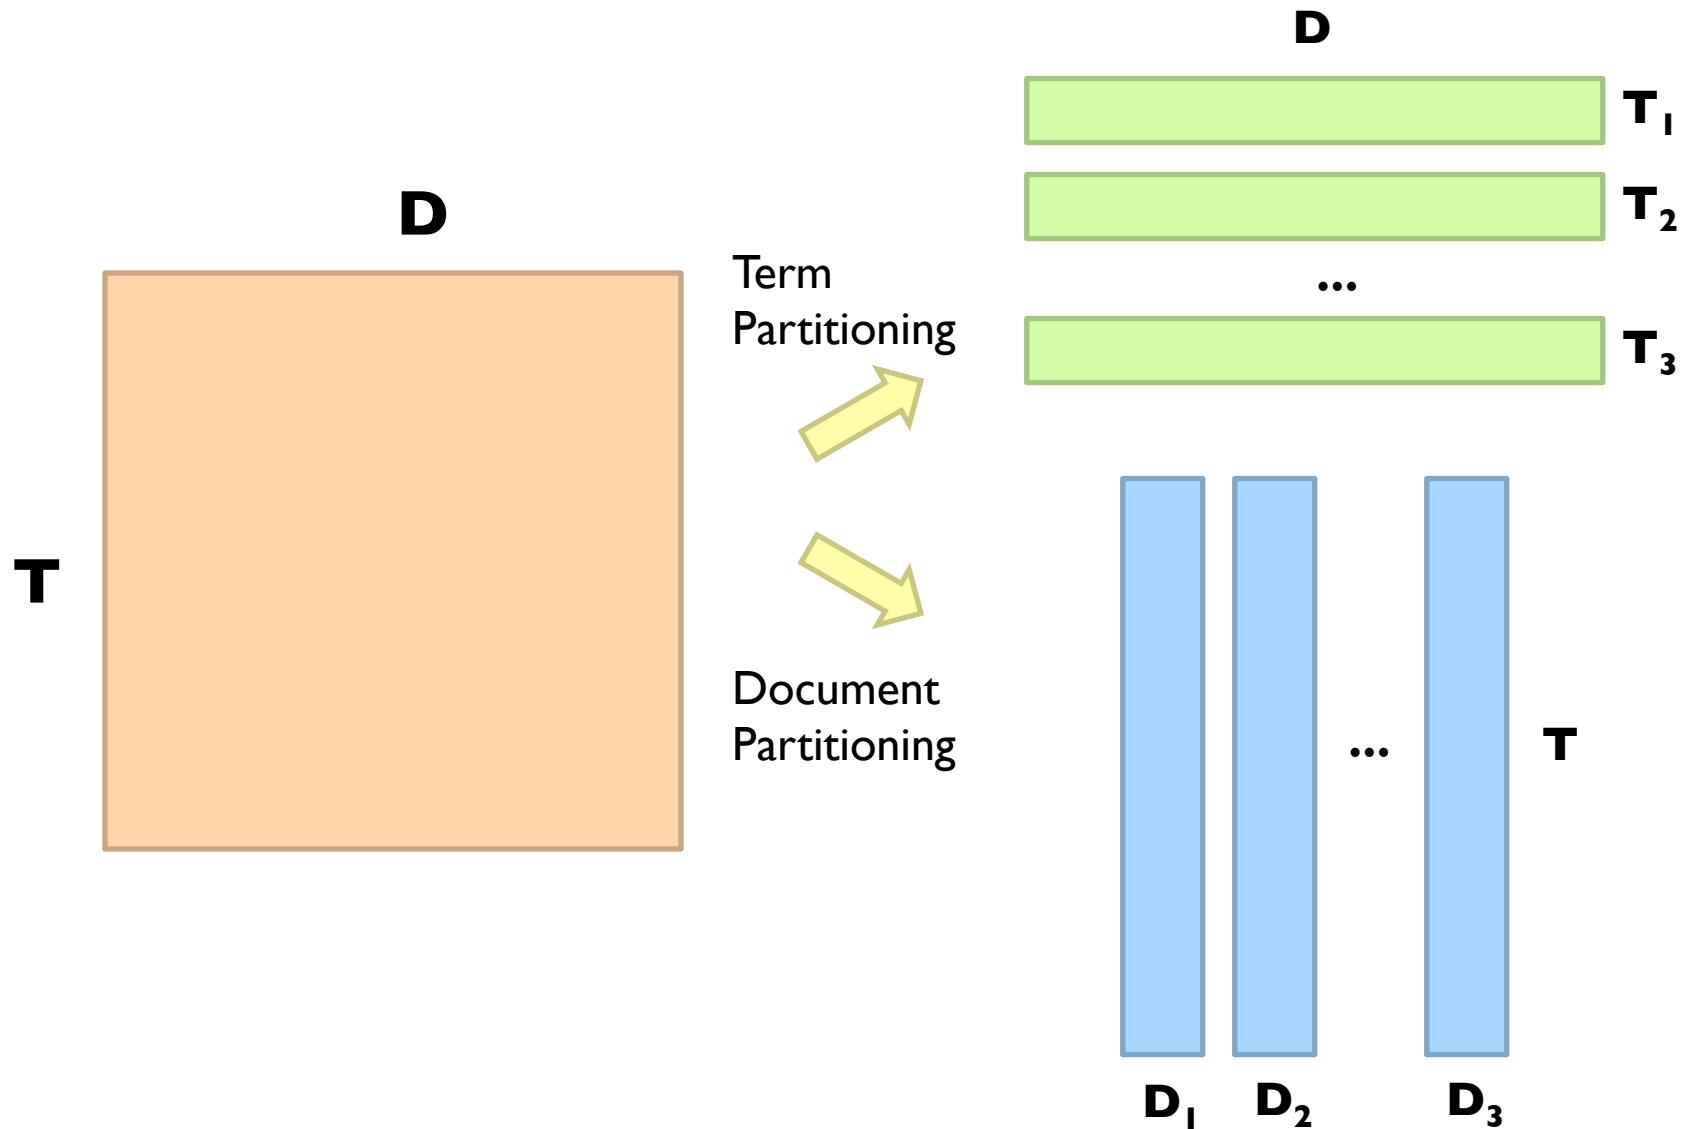

- MapReduce is fundamentally batch-oriented
 - Optimized for throughput, not latency
 - Startup of mappers and reducers is expensive
- MapReduce is not suitable for real-time queries!
 - Use separate infrastructure for retrieval...

Important Ideas

- Partitioning (for scalability)
- Replication (for redundancy)
- Caching (for speed)
- Routing (for load balancing)

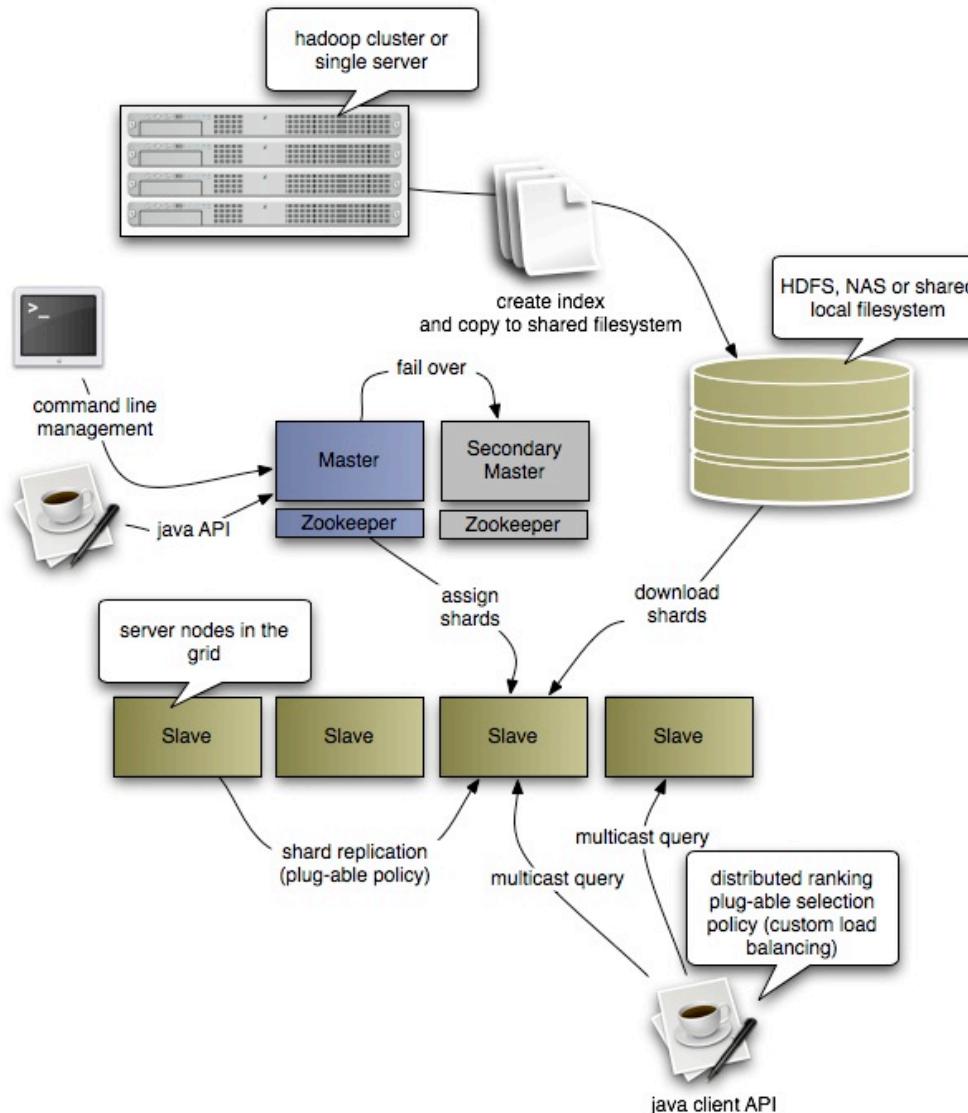

The rest is just details!

Term vs. Document Partitioning

Katta Architecture

(Distributed Lucene)

A photograph of a traditional Japanese rock garden. In the foreground, a gravel path is raked into fine, parallel lines. Several large, dark, irregular stones are scattered across the garden. A small, shallow pond is nestled among rocks in the middle ground. The background features a variety of trees and shrubs, some with autumn-colored leaves, and traditional wooden buildings with tiled roofs.
